Short notes of haloalkanes

Haloalkanes, also known as alkyl halides, are a significant class of organic compounds characterized by the substitution of one or more hydrogen atoms in alkanes with halogen atoms such as fluorine, chlorine, bromine, or iodine. These compounds are widely studied due to their diverse applications in industry, pharmaceuticals, and organic synthesis. Understanding the fundamental aspects of haloalkanes—including their structure, nomenclature, methods of preparation, properties, and reactions—is essential for students and researchers in organic chemistry. This article provides comprehensive short notes on haloalkanes, covering all critical points in a well-organized manner.

Introduction to Haloalkanes

Haloalkanes are derivatives of alkanes where one or more hydrogen atoms are replaced by halogen atoms. They are generally classified based on the number of halogens attached:

- Monohaloalkanes: containing one halogen atom

Common examples include chloromethane (CH_3Cl), bromoethane ($\text{C}_2\text{H}_5\text{Br}$), and iodoform (CHI_3).

Nomenclature of Haloalkanes

Proper naming of haloalkanes follows IUPAC rules:

Basic Nomenclature Rules

- Identify the longest carbon chain containing the halogen substituents.
- Number the chain from the end nearest to the halogen substituent to give the lowest possible number to the halogen.
- Assign the position number to the halogen substituent.
- Use the prefix (mono-, di-, tri-, etc.) if multiple halogens are present.
- Combine the names of the substituents with the parent chain name.

Examples

- Chloromethane (methyl chloride)
